Possible Airborne Laser Research, Development, and Testing at the Kazan Missile Propulsion Test Facility

An Imagery Analysis Report

NGA Review Complete

Top Secret

December 1983

Copy

56

Possible Airborne Laser Research, Development, and Testing at the Kazan Missile Propulsion Test Facility The Soviet Union appears to have conducted a laser research, development, and test program at the Kazan Missile Propulsion rest Facility from mid-1978 through early 1980. 25 The laser that was under development at Kazan may have been designed to draw both its gas supply and electric power from an RRD-3M-500 jet aircraft engine. 25 Modifications to the existing test facilities and new construction for the laser program at Kazan began in 1975. The new construction included a new exhaust system for the test cell, a new diagnostics building, and a laser test range with a target building. Based on completion of construction and the subsequent dismantlement of portions of the facility, testing of a laser could have taken place from mid-1978 through early 1980. We do not have any information to indicate the success of the laser research, development, and test program at Kazan. Information available as of 26 June 1983 has been used in this report. The author of this paper is formerly with the Office of Imagery Analysis. Comments and queries are welcome and may be directed to the Chief, Technical Systems Division, OIA, on	Approved For Release 2009/07/28 : CIA-RDP84T00896R000200170002-7

Introduction	
The Kazan Missile Propulsion Test Facilty (MPTF) is located in an isolated area 15 kilometers west of the city of Kazan (figure 1). The MPTF has been involved in the development and static testing of both liquid- and solid-fuel propulsion systems, including surface-to-air missiles and antiballistic missiles. some of the propulsion systems tested at the MPTF were developed by a Motor 25 Design Bureau (MPB) located near Aircraft Engine Plant 16 in Kazan.	5 X 1
Laser testing at the Kazan facility could 25 have occurred from mid-1978 to early 1980. When dismantlement of	5 X 1
the laser R&D facility began in early 1980, an RD-3M-500 jet	
aircraft engine was <u>observed</u> , <u>indicating</u> that it had been used in the test program.	X1
The Kazan Missile Propulsion Test Facility	
The Kazan MPTF covers approximately 70 acres and consists of two main areas, a western support area and an eastern test area, which are separated from each other by a security fence with a	
single gate The western support area is involved in 29 the assembly and checkout of propulsion systems. The eastern	5 X 1
test area is involved in propulsion-system testing and contains a high-energy laser research, development, and testing facility. The HEL R&D facility consists of the horizontal test cell 25 building (HTCB), a diagnostics building, a control building, a	5 X 1
laser range with safety panels, and a target building	25X

The HTCB

Figure 4

The HTCB is similar to a horizontal test cell called the aerodynamic and propulsion test unit (APTU) at the Arnold Engineering Development Center, Arnold Air Force Station, Tullahoma, Ten-Like the APTU, the HTCB is probably a true nessee (figure 4). air-breathing testing facility used for temperature test propulsion systems and rockets while simulating actual flight conditions at supersonic velocities. Also like the APTU, it has a high-pressure air storage reservoir and regenerative storage Items observed to be associated with the HTCB include collapsible conduits, an RD-3M-500 jet engine, jet engine housings, aircraft fuel tanks, and special air conduits.

The HTCB A diffuser/exhaust duct and craneway are located at the high. east end, and a one-story wing is located on both the north and south sides. The main part of the building is a rectangular high and houses a test bay The main part of the HTCB probably also houses cell offices, an instrumentation room containing monitoring equipment, computer area, an electrical equipment room, a mechanical equipment room, and a shop room with a tool crib area.

Collapsible Conduit Associated with the HTCB. Sections of a
collapsible conduit
This was the first time that this type of conduit had been noted at a Soviet laser range. The sections, which have bellows-like
folds, could have been expanded to connect the HTCB to the
diagnostics building We believe that the conduit is
used to enclose the laser beam path from the HTCB to the diag-
nostics building during beam propagation. The use of a conduit for beam propagation would serve as both a safety measure and a
means of eliminating any atmospheric interference to the laser
beam before it reaches diagnostic equipment.
the collapsible conduit was removed.

Aircraft Engine and Air Conduit

Associated with the HTCB. On

two engine
housings, used for mounting jet
engines to an aircraft, were

housings, used for mounting jet engines to an aircraft, were observed on the HTCB exhaust apron. The engine housings had the same overall dimensions as those used to hold the RD-3M-500 aircraft engine. In December 1980, after the HEL R&D program had ended, an RD-3M-500 aircraft engine and an air conduit with a mixing chamber that probably contained expansion nozzles were observed for the first time at the HTCB

Three charred air conduits of the same configuration, but with mixing chambers, were discarded in the boneyard, and aircraft engine fuel tanks were discarded at the end of the exhaust apron.

These sightings of an aircraft engine and associated air conduits and fuel tanks at the HTCB indicate that an aircraft engine was being used in the HTCB while an HEL R&D program was under way.

The Diagnostics Building

The diagnostics building is a gablesmall, rectangular, roofed structure erected on the HTCB's exhaust apron, between the curved end of the diffuser/ exhaust duct and a dirt back-The building has an stop. annex on its east and west sides and has been canted at an angle to the HTCB. The angle places the front of the diagin alignment nostics building with the graded laser range,

safety panels, and target building. The positioning of the diag- nostics building also places an opening on its west wall in direct line-of-sight with an opening in the HTCB.	25X1 25X1
At the time the diagnostics building was being fitted out, a number of diagnostic artifacts, probably optics/mirror mounts, were observed near the building. Elevated conduit sections, possibly beam ducts for use between diagnostic equipment, were also present	25X1
An elevated pipeline/conduit connects the diagnostics building to the first two banks of gas bottles along the south side of the HTCB. The pipeline probably supplies compressed air to the diagnostics building for such purposes as purging equipment, floating an optical bench, and conditioning the beam path. Another pipeline/conduit that runs along the ground between the two buildings probably supplies electric power to equipment in the diagnostics building. A second elevated pipeline/conduit connects the diagnostics building to the target building. This pipeline/conduit may carry electric cables for supplying power to the target building and to provide a data link between the two buildings. [11]	25X1
A portal on the side of the diagnostics building facing downrange has a louvered cover. The cover and is probably hinged so that it can swing open to the side. The	25 X 1
louvers allow for openings It is possible that the louvers can be individually opened and may protect the diagnostics building from reflected radiation from	25X1
the targets downrange during alignment procedures.	25 X 1 25 X 1

Laser Range

The laser range slopes upward from the diagnostics building to the target building on an incline of about 4 degrees (figure 11). The range and has six safety

panels positioned along it. Each safety panel

The diameter of the and contains a circular hole. holes decreases the farther the panels are from the diagnostics Except for the last panel, each panel is approximately twice as far from the diagnostics building as the preceding The close spacing of the panels near the source of the propagating laser beam suggests that they serve a safety role. Accidental direct illumination by the laser, caused by beam misalignment, can be prevented by the outer opaque portions of The closer the first few panels are to each other, the panels. the less misalignment that is permitted. The surrounding area would be shielded from direct radiation by the series of panels and the target building itself. The panels would also help to block a portion of radiation reflected or scattered by obstructions along the beam path to the target building. Decreasing hole size is what one would expect for a fixed beam. [12,13] safety panels' measured distances from the diagnostics building and the progressive decrease in diameter of the holes in the panels agree favorably with the required calculated diameters, at equivalent distances, for a focused beam of

exiting the portal of the diagnostics building

	25X ² 25X1
	25/(1
The opening in several of the panels has occasionally been	
observed filled, suggesting that the panels hold removable instrumentation packages for laser beam diagnostics. Such packages have been used at US ranges for measuring intensity profiles of high-energy laser beams. One such US package, called a holey plate thermocouple array, consists of calorimeter disc thermocouples located behind a regular array of holes in a metal or graphite piece (figure 12). These packages can be	
moved from panel to panel to measure the beam profile at various distances. [11]	25 X ²
A pole with a short perpendicular arm was observed at the edge of the HTCB exhaust apron in front of the diagnostics building. The pole probably serves as a support for meteorological sensors. A solid fenceline on both sides of the range near the target building extends from the building to just past the fifth safety panel. This fence is probably intended to block any possible reflective scatter of the beam from the fifth and sixth safety panels or the target building.	

25X1

Top Secret

25X1

Figure 12
Holey Plate Thermocouple Array

What appears to be an observation stand is positioned to the east side of the range near one of the solid fences. The stand consists of two walls and flooring. The west wall facing the range is higher than the east wall and has large rectangular openings which may serve as windows. The north and south sides of the stand are open and the top is covered with canvas.

The Target Building

The target building consists of two parts

The first part to be constructed probably contains support equipment such as storage tanks for cooling water. The part of the target building that is in direct alignment with the safety panels rests on a poured concrete base next to the support area and is connected by an elevated pipeline to the diagnostics building. The pipeline probably carries electric cables--providing power and a data link--to monitoring equipment and probably to a calorimeter positioned on the concrete base.

The modifications to the HTCB that began in 1975 were probably to accommodate an RD-3M-500 aircraft engine with a special air conduit in the test cell. The larger-than-usual diameter of the special air conduit indicates that it has a mixing chamber that probably contains expansion nozzles. Computer graphics,

illustrate how the two test components could fit together (figure 13). As shown, the engine is

perfectly matched to the special air conduit. The computer graphics also show that the air conduit has what could be a bleeder valve, which controls the amount of engine exhaust entering the mixing chamber in the conduit. When the bleeder valve is completely closed, all engine exhaust flows through the When the valve is open, some engine exhaust mixing chamber. could bypass the mixing chamber and exit directly through the In the test cell, the open end of the diffuser/exhaust duct. special conduit extends into the diffuser/exhaust duct

25X1

25X1

This could permit a laser, located in the mixing chamber, to be electrically powered by the jet engine and to use the jet engine exhaust gases as its gas supply. We believe that the RD-3M-500 installed in the HTCB performed both functions, because using a test-cell building to run a jet engine only as a turbogenerator would seem to involve excessive modifications, time, and expense for the gains expected.

25X1

The optics/mirror mounts observed at the diagnostics building probably used focus to the beam being through the six safety panels to the target building. The Soviets probably studied the focused beam's energy distribution and effects in the atmosphere. The limited flexibility of the range and the hole diameters in the panels indicate that the range is primarily intended for the development, initial testing, and checkout of the laser device. Tests that could be done at this range include studying the gas flow characteristics of a laser, studying the interaction between a laser and its optical systems, and testing a laser to be sure it is operating according to specifications.

25X1

25X1

We do not have any information to indicate the success of the laser research, development, and test program at Kazan.

25X1 25X1

it may have been part of the R&D effort for the probable high-energy laser system that was installed in the early 1980s on a modified IL-76 (Candid) transport aircraft at Taganrog airfield. Since September 1982, this aircraft has been observed at Shchelkovo airfield near Moscow where there are newly built facilities suitable for conducting ground tests of an airborne HEL.

25X1 25X1

Estimated Time of Testing at the Range

Based on the timing of construction modifications and dismantlement, we can estimate the period of time when laser testing could have occurred at Kazan. New construction and modifications to the existing structures at the laser range began in May 1975 and were completed in April 1978. Dismantlement of the safety panels began in May 1980. Therefore, testing could have taken place between April 1978 and May 1980.
